Hw 3 - Vectors

## SOLUTIONS

1. Warm up. Is the angle between $\mathrm{v} 1=<2,3,2>$ and $\mathrm{v} 2=<-3,1,2>$ obtuse or acute?

Solution: Since $\mathrm{v} 1 \cdot \mathrm{v} 2=1>0$, the angle is less than 90 degrees (acute)
2. For what values of $\alpha$ is $\mathbf{a}$ orthogonal to $\mathbf{b}-\alpha \mathbf{a}$ ? What about the special case where $\|\mathbf{a}\|=1$ ? The case where $\|\mathbf{a}\|=0$ ?

Solution: $\quad$ For a orthogonal to $\mathbf{b}-\alpha \mathbf{a}$, we need $\mathbf{a} \cdot(\mathbf{b}-\alpha \mathbf{a})=\mathbf{0}$ which gives $\mathbf{a} \bullet \mathbf{b}-\alpha \mathbf{a} \cdot \mathbf{a}=\mathbf{0}$ and $\alpha=\mathbf{a} \cdot \mathbf{b} / \mathbf{a} \cdot \mathbf{a}$.

If $\|\mathbf{a}\|=1$, then $\alpha=\mathbf{a} \cdot \mathbf{b}$
If $\|\mathbf{a}\|=0$, then $\alpha$ is not defined (if the length of $\mathbf{a}$ is zero, then $\mathbf{b}-\alpha \mathbf{a}=\mathbf{b}$, and if $\mathbf{b}$ is arbitrary, then $\mathbf{a}$ and $\mathbf{b}$ need not be orthogonal.
3. Given a helix curve in parametric vector form as $\mathrm{P}(\mathrm{t})=<\mathrm{r}^{*} \cos (\mathrm{t}), \mathrm{h}^{*} \mathrm{t}, \mathrm{r}^{*} \sin (\mathrm{t})>$, what is the tangent vector T to the curve? What is the normal vector N (which is $\mathrm{T}^{\prime}$ )? And what is the binormal vector B (which is $\mathrm{T} \times \mathrm{N}$ )?

Solution: Given $\quad \mathrm{P}(\mathrm{t})=<\mathrm{r}^{*} \cos (\mathrm{t}), \mathrm{h} * \mathrm{t}, \mathrm{r} * \sin (\mathrm{t})>$
We have

$$
\mathrm{P}^{\prime}(\mathrm{t})=<-\mathrm{r}^{*} \sin (\mathrm{t}), \mathrm{h}, \mathrm{r}^{*} \cos (\mathrm{t})>
$$

$$
\mathrm{P}^{\prime} ’(\mathrm{t})=<-\mathrm{r}^{*} \cos (\mathrm{t}), 0,-\mathrm{r}^{*} \sin (\mathrm{t})>
$$

And now

$$
\begin{aligned}
\mathrm{P}^{\prime}(\mathrm{t}) \times \mathrm{P}^{\prime \prime}(\mathrm{t})= & \left|\begin{array}{ccc}
\mathrm{i} & \mathrm{j} & \mathrm{k} \\
-\mathrm{r}^{*} \sin (\mathrm{t}) & \mathrm{h} & \mathrm{r}^{*} \cos (\mathrm{t}) \\
-\mathrm{r}^{*} \cos (\mathrm{t}) & 0 & -r^{*} \sin (\mathrm{t})
\end{array}\right| \\
& =<-\mathrm{rh} * \sin (\mathrm{t}), \mathrm{r}^{\wedge} 2 *\left(\cos ^{\wedge} 2+\sin ^{\wedge} 2\right), \mathrm{rh} * \cos (\mathrm{t})> \\
& =<-\mathrm{rh} * \sin (\mathrm{t}), \mathrm{r}^{\wedge} 2, \mathrm{rh}^{*} \cos (\mathrm{t})>
\end{aligned}
$$

4. For the previous problem the appropriate range of $t$ isn't important - for actually drawing a helix, picking the range of $t$ to appropriate scale $h$ and the number of twists is important. Redo the helix equation so as t goes from 0 to 1 , the helix makes N full turns and rises to a height h .

Solution: Given the height h , radius r , and the number of turns N , the equation would be:
$\mathrm{P}(\mathrm{t})=<\mathrm{R} * \cos (2 \pi \mathrm{Nt}), h \mathrm{ht}, \mathrm{R} * \sin (2 \pi \mathrm{Nt})>$
5. For the lecture example for the midpoint of a triangle, calculated by first blending the line segment between two points P 0 and P 1 , and then blending that equation with the third point P 2 ,
show that (a) if you hold s constant then varying $t$ sweeps out a line, and (b) those lines of constant s are parallel to the line from P0 to P1.

Solution: The equation for the blending is developed as following:
Blending P0 and P1 gives the following, with $\mathrm{v}=\mathrm{P} 1-\mathrm{P} 0$

$$
\mathrm{m}(\mathrm{t})=(1-\mathrm{t}) \mathrm{P} 0+\mathrm{tP} 1=\mathrm{P} 0-\mathrm{tP} 0+\mathrm{tP} 1=\mathrm{P} 0+\mathrm{t}(\mathrm{P} 1-\mathrm{P} 0)=\mathrm{P} 0+\mathrm{tv}
$$

Blending $\mathrm{m}(\mathrm{t})$ and P 2 gives $\mathrm{m} 0(\mathrm{~s}, \mathrm{t})=(1-\mathrm{s}) \mathrm{m}(\mathrm{t})+\mathrm{sP} 2$

$$
\begin{aligned}
& =(1-\mathrm{s})(\mathrm{P} 0+\mathrm{tv})+\mathrm{sP} 2 \\
& =\mathrm{P} 0+\mathrm{tv}-\mathrm{s}(\mathrm{P} 0+\mathrm{tv})+\mathrm{sP} 2 \\
& =(\mathrm{P} 0-\mathrm{sP} 0+\mathrm{sP} 2)+(1-\mathrm{s}) \mathrm{tv} \\
& =\mathrm{P}+\mathrm{t}(\mathrm{cv}) \quad \text { with } \mathrm{P}=(\mathrm{P} 0-\mathrm{sP} 0+\mathrm{sP} 2), \mathrm{c}=(1-\mathrm{s})
\end{aligned}
$$

Assuming s is constant, then P is a fixed point, and (1-s) is constant so cv is scaled version of $v$.

Since $m 0(s, t)=P+t(c v)$ with $s$ constant, then $m 0(s, t)$ is a line Since each of the lines generated as we change $s$ is in the direction (cv) or $v$, the lines are all parallel (two parametric lines are parallel if they have the same vector).

The key to the solution is rewriting the blending equation in terms of the vector v .
6. If you have $\mathrm{a} \cdot(\mathrm{bxc})=0$, what does it mean for the relationship of the three vectors?

Solution: It means they are co-planar and don't span 3D space. Since bx c is normal to both b and c , then if a is normal to bxc then it is in the same plane as b and c . A single plane is defined if two or three of $\mathrm{a}, \mathrm{b}$ and c are not degenerate vectors (equal to the zero vector). Otherwise the three vectors define a single plane. $\mathrm{a} \cdot(\mathrm{bxc})$ is called the triple scalar product.
7. Find the normal vector to the triplets below, if it exists:
a) $\quad \mathrm{P} 1=(1,1,1), \mathrm{P} 2=(1,2,1), \mathrm{P} 3=(3,0,4)$
b) $\quad \mathrm{P} 1=(8,16,2), \mathrm{P} 2=(-8,-16,-2), \mathrm{P} 3=(4,8,1)$

Solution:
a) $\quad \mathrm{v} 1=\mathrm{P} 2-\mathrm{P} 1=<0,1,0\rangle \quad \mathrm{v} 2=\mathrm{P} 3-\mathrm{P} 1=<2,0,3>$ and $\quad \mathrm{v} 1 \mathrm{xv} 2=<3,0,-2>$
b) $\quad \mathrm{v} 1=\mathrm{P} 2-\mathrm{P} 1=<-16,-32,-4>\mathrm{v} 2=\mathrm{P} 3-\mathrm{P} 1=<-4,-8,-1\rangle$
and

$$
\mathrm{v} 1 \mathrm{x} v 2=<0,0,0\rangle
$$
